Abstract

Telemedicine is a digital platform that provides medical services to people without limitations of place and time. The physician can get the data history of the rehabilitation directly from the patient for getting the diagnosis suitable for therapeutic plans. This study presents the development of the program includes website support with a user database and real-time feedback. Usage history data is collected from the device and displayed on the website for the physician. In general, the therapy process, which uses the continuous passive motion device for knee, is accomplished in a hospital in a rehabilitation department. During the Coronavirus pandemic, getting to a hospital to receive the therapy process is more intense than before due to a higher risk of getting infected and inefficient medical services. According to these reasons, telemedicine resolves the problem.
